Hydrologic Engineering Center

Hydrologic Modeling System
HEC-HMS

Release Notes

Version 2.2.1
October 2002

Approved for Public Release – Distribution Unlimited
Introduction

Version 2.2.0 of the Hydrologic Modeling System (HEC-HMS) was completed in August 2002 and released for general use shortly thereafter. A major problem was found in printing summary tables and time-series tables. The problem has been repaired so that tables can now be printed correctly. Two minor problems were also found and repaired. A problem was found in the optimization manager but has not been repaired at this time. This release is available for computers running the Microsoft Windows 2000/NT/98/95 operating systems or the Sun Microsystems Solaris operating system.

Development of the software is ongoing. The entire program is currently being converted from the C++ programming language to the Java language. New snowmelt simulation capabilities will be added to the meteorologic model in the future. Further details may be found in the Future Plans section.

The Technical Reference Manual for Version 2.0 continues to accurately describe the mathematical models included in the program. The User's Manual labeled Version 2.1 continues to accurately describe the use and application of the program. Supplemental description of the new reservoir features added at Version 2.2.0 can be found in the release notes for that version.

The installation program and all documentation are available on the HEC website at http://www.hec.usace.army.mil/.

Installation

The installation package is designed to be easy to use. If you have never installed the HEC-HMS program before, the installation package will take you through the steps of selecting a directory for the program files, a directory for the sample project files, and making other settings. If you have installed the HEC-HMS program before, the installation package will automatically detect the previous version and upgrade to the new release. Use the following steps to install or upgrade the program:

1. Download the installation package from the HEC website to a temporary folder on the computer. Alternately, insert the provided CD-ROM or other media in the appropriate drive.

2. Run the installation program. In Windows Explorer, double-click the icon for the installation program.

3. Follow the on-screen prompts to install or upgrade the program. Be sure to reboot the computer before using the HEC-HMS program if this is the first installation of the program.

New Users

The program has been designed to be easy to use. However, an understanding of how the program works is critical to producing accurate results. It is suggested that a new user read Chapter 3 of the User's Manual and Chapters 2 and 3 in the Technical Reference Manual before attempting to start and use the program. Subsequently, start the program and construct the example application contained in Chapter 10 of the User's Manual. These chapters provide the fundamental instruction necessary to effectively use the program.
Experienced Users

The User's Manual contains information about using each of the computational methods included in the program. A Technical Reference Manual is also available to describe the theoretical basis for the methods included in the program. It is recommended that experienced users read the topics, both in the User's Manual and Technical Reference Manual, for methods used frequently.

Closed Defects

A total of 3 defects have been repaired since the release of Version 2.2.0. A brief description of each repaired defect follows:

1. The program would crash when attempting to print summary tables or time-series tables of element run results. The crash no longer occurs and the tables are printed correctly.

2. The column label for the constant-monthly baseflow method always showed "CFS", regardless of the basin model unit system. The data were interpreted in the context of the current unit system so that only the label was incorrect when using the System International unit system. The column label is now shown correctly as "CMS" for System International and "CFS" for U.S. Customary.

3. The program would stop responding when attempting to import a basin or meteorologic model, if the model was located in the project directory. The import proceeded correctly if the model was imported from a different directory. The model is now correctly imported into the project regardless of where the file is stored on the computer.

Open Defects

A total of 7 major and minor defects are currently open and undergoing investigation and repair. Future versions of the program should solve most of these issues. The following defects are open:

1. The program can only print using a PostScript language print driver. Attempts to use other print driver languages, for example Printer Control Language (PCL), will result in many pages of output containing seemingly random text characters. PostScript print drivers are available for almost all laser printers. Contact the printer manufacturer for the latest PostScript print driver, or download it from their website.

2. The program may crash under some conditions when attempting to graph element results. The crash may occur before the graph has finished drawing, while moving or resizing the graph, or when closing a graph. The crash occurs whenever diversion flow from a diversion element is connected downstream to another element in the basin model. The crash does not occur if the diversion flow is not connected downstream. The exact cause of the problem is unknown at this time.

3. Optimization results will be lost if any of the hydrologic elements used in an optimization trial are renamed in the supporting basin model. Additional problems will occur if the loss, transform, or baseflow method is changed in a subbasin after it has been added to an optimization trial. Generally speaking, the basin model used in an optimization run and
trials should not have elements added, renamed, or removed, and the methods selected for the elements should not be changed. The exact cause of the problem is unknown at this time.

4. The program will crash if the parameters in an optimization trial are reordered after a new trial is created and before it is computed for the first time. The exact cause of the problem is unknown at this time.

5. The program may become unresponsive or crash under some conditions when using the mouse to very quickly open and close screens other than the basin model screen. The instability becomes more intense if selections are made or parameters entered on the screen when quickly opening and closing the screens. The problems disappear when the program is used at a normal pace.

6. Subbasin results for soil moisture accounting may not appear exactly as anticipated. The soil moisture accounting time-series table always shows results for the "first" subbasin regardless of the subbasin selected when the results were requested. The selection list in the upper right corner of the time-series table can be used to switch to any subbasin using the soil moisture accounting loss method.

7. The optimization manager will not perform well when attempting to optimize the number of routing steps in the linear reservoir baseflow method. The trial may give poor results or the program may crash while the trial is optimizing. The optimization manager continues to function correctly when the number of steps is not selected for optimization.

Future Plans

In terms of look and feel, the current version of the program has changed little from the original Version 1.0 release in March 1998. The design of the interface was implemented by using the C++ programming language and the Galaxy development library. The library allowed nearly identical versions of the program to run on both Microsoft Windows and Sun Solaris operating systems even though they use conflicting methods for rendering images on the computer display. At the time, the library represented state-of-the-art development techniques for deploying software to multiple operating systems.

The software development industry has changed radically since the HEC-HMS project began in 1992. At that time it was very difficult to create software designed to operate on multiple operating systems if a graphical user interface was required. The intervening years between then and now have brought about the Java programming language. Contrary to earlier languages or development systems, the Java language is specifically designed to look and operate the same on a wide variety of operating systems without any additional work by software developers. The advantages of the Java language are so great that in 2000 the decision was made to adopt Java for future development work in replacement of C++ and the Galaxy library.

Version 2.2.0 will be the terminal release using the C++ programming language and the Galaxy library. All future releases, beginning with Version 3.0, will be developed using the Java language. A significant amount of work has already been completed to convert the existing computation engine to Java. Instead of replacing the existing interface with one written in Java using a similar look and feel, the development team has taken this opportunity to critically examine the
interface and redesign it as necessary. The final design is complete and compares nicely with other engineering and scientific software programs from commercial companies. Work is under way to implement the new design for the interface and an approximate date for the beta release of Version 3.0 is fall 2003.

Version 3.0 will contain all of the capability present in Version 2.2.0 and will also add snowmelt simulation to the meteorologic model. Algorithms originally developed for the Distributed Snow Process Model (DSPM) are being adapted for use in HEC-HMS. DSPM is a temperature index method that has already been successfully applied in a number of projects (Daly et al., 1999). The algorithms represent a reasonable advancement over snow melt algorithms included in HEC-1 and will support both lumped subbasins using unit hydrograph or kinematic wave methods, and gridded subbasins using the ModClark method. Unfortunately, the advancements in algorithm design will preclude importing HEC-1 files set up for snow melt simulation.

As time allows, features in addition to snowmelt simulation will also be added to Version 3.0 before its first release. These features may include customizable reports for basin model, meteorologic model data, and run results, or automatic depth-area reduction analysis. The first priority is to release Version 3.0 in a timely manner with the temperature index snowmelt simulation. Extensive beta testing will be undertaken prior to release of the new interface system.

Additional features are being planned for inclusion after the Version 3.0 is released. These may include: additional reservoir capabilities for modeling interior flood zones, energy budget snowmelt simulation, user scripting to automate simple tasks, frequency curve generation, animated graphs of gridded precipitation and runoff results, additional optimization features, and user extensions for adding new methods such as reach routing.

A comprehensive program validation guide is currently under development and will be published when complete. The guide gives detailed information about the tests used to determine the accuracy of the mathematical models included in the program, for example, the SCS curve number loss method. The section for precipitation methods is currently complete in draft form. Sections for junctions, sinks, diversions, reservoirs, and some reach routing and loss rate methods are also complete in draft form. It was found that HEC-HMS accurately implements all features in the tested methods.

**Documentation**

The *Hydrologic Modeling System HEC-HMS: User's Manual* contains extensive information on installing and using the program. An example application is included to illustrate the steps necessary to produce results.

The *Hydrologic Modeling System HEC-HMS: Technical Reference Manual* contains information on how to use the various methods included in the program. The scientific origin and equation derivations are presented for each method. Specific solution algorithms for a method are discussed when necessary for a complete understanding. Application and parameter estimation for each method is also included.

The *Hydrologic Modeling System HEC-HMS: Applications Guide* is currently under development and will be released soon. The guide will provide detailed information on the application of the program to a wide variety of studies. Study types to be addressed include urban flooding, flood frequency, flood-loss
reduction, flood warning system planning, reservoir spillway adequacy, and environmental restoration. Details for each study type will include typical objectives, required hydrologic information, modeling options and selection criteria, model configuration, design criteria where appropriate, and results presentation. A case study will illustrate each study application.

The online help system within the program contains topics describing each screen of the graphical user interface.

Support Policy

Technical support for program users within the Corps of Engineers is provided through an annual subscription service. Subscribing offices can expect full support from HEC staff in the routine application of the program. Users are strongly urged to consult with HEC staff on the technical feasibility of using the program before beginning a project with unique requirements such as grid-cell hydrology, snow melt, or continuous simulation. Extended support for large or complex projects can be arranged under a separate reimbursable project agreement.

Support can not be provided to users outside the Corps of Engineers. Domestic and foreign vendors are available that provide fee-for-service support similar to the support provided to subscribing Corps offices. Such service agreements are between the user and the vendor and do not include HEC staff. Vendors do contact HEC on behalf of their users when unusual problems or errors are encountered. A list of vendors can be found at [http://www.hec.usace.army.mil/](http://www.hec.usace.army.mil/).

Reporting of suspected program errors is unrestricted. We are continuously working to improve the program and possible bugs should always be reported. Reports should include a written description of the steps that lead to the problem and the effects that result from it. We will reply to all correspondence concerning program errors.

Request support or report program errors through the following channels:

- Call +1-530-756-1104, 7:30 am to 4:30 pm PT Monday through Friday.
- Fax +1-530-756-8250 any time.
- Write to U.S. Army Corps of Engineers, Institute for Water Resources, Hydrologic Engineering Center, 609 Second Street, Davis, CA 95616-4687 USA.
- Send email to hms@usace.army.mil on the internet.
